## KERNEL NETWORKS FOR LEARNING FROM SENSOR DATA

Roman Neruda, P. Vidnerová V. Kůrková MC Substitute, roman@cs.cas.cz
Institute of Computer Science, Academy of Sciences
of the Czech Republic, Prague

## Outline

- Kernel networks
- Theoretical properties
- Composite and product kernels
- Learning algorithms
- Beyond parameter setting
- Evolutionary computing
- Data
- Results
- Discussion
- Challenges

EUROPEAN COOPERATION IN SCIENCE AND TECHNOLOGY

## Learning from data

- Problem:

Given set of data samples:

$$
\left\{\left(x_{i}, y_{i}\right) \in R^{d} x R ; i=1, \ldots, N\right\}
$$

Recover the unknown function $f(\mathbf{x})$ $f: R^{d}->R$
(or find a best approximation)

- Supervised learning
- Regression
- Classification
- Prediction

## Regularization theory

- Empirical risk minimization:
- Find a solution $f$ that minimizes $H(f)=\Sigma\left(f\left(\boldsymbol{x}_{i}\right)-y_{i}\right)^{2},(i=1 \ldots N)$
- Generally ill-posed problem
- Choose a solution according to a priori knowledge
- (what should f look like? - e.g. smooth, small oscilations,)
- Regularization:
- Add a stabilizer $A(f)$ :
- $H(f)=\Sigma\left(f\left(\boldsymbol{x}_{i}\right)-y_{i}\right)^{2}+\gamma A(f),,(i=1 \ldots N)$
- $A(f)$ - based on Fourier transform divided by a kernel function
- $A(f)$ - defined by a norm on reproducing kernel Hilbert space (RKHS)
- $f(x)=\Sigma w_{i} K\left(\boldsymbol{x}-\boldsymbol{x}_{i}\right)$, for positive $K$, where $(\gamma \boldsymbol{I}-\boldsymbol{K}) \boldsymbol{w}=\boldsymbol{y}$

## Regularization networks

- f can be represented by a feed-forward network with one hidden layer of units computing K
- Function K is called basis or kernel function
- choice of K represents our knowledge or assumption about the problem
- choice of K is crucial for the generalization performance of the network

## Regularization networks

- Basic Algorithm:
- 1. set the centers of kernel functions to the data points
- 2. compute the output weights by solving linear system

$$
(y I+K) \boldsymbol{w}=\boldsymbol{y}
$$

- Pros:
- easy, fast
- Cons:
- choice of $y$ and $K$ (and its parameters) is crucial for performance
- ... and it is data dependent: (no-free-lunch theorem)

Inverse Multi-quadratic

Sigmoid

Thin Plate Spline

Multi-quadratic

## Sum (combination) kernels

- Aronszajn theory: RKHS is closed w.r.t. linear combination

$$
K(x, y)=\alpha K_{1}(x, y)+\beta K_{2}(x, y)
$$

- Each unit is composed of a two linearly combined kernels
- More parameters to set
- Possiblity to combine different kernel function
- Possibility to retain detailed approximation while having good generalization

## Product kernels

- Aronzsajn: product of two RKHS is in RKHS

$$
K\left(x_{1} x_{2}, y_{1} y_{2}\right)=K_{1}\left(x_{1}, y_{1}\right) \cdot K_{2}\left(x_{2}, y_{2}\right)
$$

- Each unit has two kernel functions operating on different subsets of inputs
- Heterogenous data:
- Different properties of attributes
- Processed by different kernels
- Even more parameters (input split)

## Simple learning

1. Expert knows/miracle (statistics) happens:

- Type of kernel function, pairs for combinations and products
- The regularization parameter y
- For combination kernels, the parameters of combination
- For product kernels, the input split into two subsets

2. Then, solve a linear system

OR

1. Use tailored search algorithms to set the metaparameters

- Such as evolutionary algorithm

2. Combine it with the linear part of the algorithm

## Evolutionary learning

## Evolutionary learning

- Population based search heuristics
- Prone to local optima
- Suitable for search of heterogeneous spaces/problems
- Does not require additional information such as gradients
- Encoding of metaparameters of kernel networks
- Floating point parameters together with binary input splits and integer indices of kernel types
- Standard operations of arithmetic crossover for floats, one point crossover for discrete variables, and mutations
- Selection based on cross-validated performance of the fullytrained model

## EXPERIMENTS

## Data

- The dataset contain tens of thousands measurements of gas multi-sensor MOX array devices recording concentrations of several gas pollutants.
- Collocated with a conventional air pollution monitoring station that provides labels for the data.
- The data are recorded in 1 hour intervals.
- S. De Vito et al.

Table 1. Overview of data sets sizes.

| Task | train set test set |  |  | Task | train set test set |  |  |
| :--- | :---: | :---: | :--- | :--- | :---: | :---: | :---: |
| sparse CO | 1224 | 6120 |  | CO i1-5 | 1469 | 5875 |  |
| sparse NO2 | 1233 | 6160 |  | NO2 i1-5 | 1479 | 5914 |  |
| sparse NOx | 1233 | 6163 |  | NOx i1-5 | 1480 | 5916 |  |

## Preliminary experiments - overview

## WHAT WORKED?

## Conclusions

- Modeling with kernel networks works well for sensor data
- The evolutionary search for parameters was able to find better models in comparison to ad-hoc/standard techniques
- The resulting models are quite small and fast

## Challenges

- Missing data
- Semi supervised learning (S. de Vito)
- Surrogate models
- Large data
- Meta-learning takes long time
- Preprocessing
- Expert insight into data
- Influence of factors like time of the year, ...
- Ensemble models
